## **PORTABLE MULTIMODE DISPLAY DEVICE**

### Field of the Invention

The present invention relates generally to a portable device and, more specifically, 5 to a portable device having a high-resolution display for viewing still and video images and having multi-media capability.

### Background of the Invention

People that have a portable lifestyle would appreciate instant access to a large 10 amount of information via a portable device, such as a mobile phone, personal data assistant, communicator and the like. While it is a common practice to use a low-resolution liquid-crystal display (LCD) panel to display network information and text messages, it is preferred to use a high-resolution display to browse rich information content of text and images. The high-resolution displays typically have at least SVGA 15 (800x600 pixels) resolution and are of an active matrix type. They can be used for direct view displays or virtual displays. The virtual displays are known as Near Eye Displays (NED). Direct view displays can be visible simultaneously to several observers, whereas the virtual display is only for one person. Virtual displays consist typically of a microdisplay and imaging optics. They can be monocular or binocular. The perceived 20 image in a virtual display can be larger than the device itself. The usability of the virtual display depends very much on the performance of the microdisplay and optics.

The size of the beam of light emerging from imaging optics towards the eye is called exit pupil. In NED, it is typically of the order of 10 mm in diameter. The ease of the use of a virtual display would be improved significantly if the exit pupil were 25 enlarged. When the exit pupil is large enough, the device can be at a distance from the eye, and the display would not then be NED, but would still be a virtual display. In this context, this operating mode is called Window-mode.

The pixel pitch, which is resolvable to the human eye, determines the necessary size of a high-resolution direct view display. This means, in practice, that the size of the 30 display would be larger than the small portable device itself. In addition to virtual display, projection of an image also provides a method to overcome this dilemma. However, the

power consumption of the illumination would be too high for a battery operated portable device, even if the projected image is only about 10 inches in diagonal. It is advantageous and desirable to provide a method that can show high-resolution images in reasonable size. In battery-operated devices, the window or projection mode is desirable. The power 5 consumption in window mode is slightly larger than in NED mode, but is reasonable for a battery operation. The power consumption in projection mode depends on the size of the projected image. Thus, in battery operation the projected image size would be limited. If the projected image is the size of a typical computer monitor or larger, a connection to an external light source is necessary.

10

#### Summary of the Invention

The primary objective of the present invention is to use a portable device having a display system, which can work in several display modes, using a microdisplay as an image source and enlarging the image by different optical arrangements corresponding to 15 different display modes.

The first mode of operation is a virtual Near Eye Display (NED), which typically uses a microdisplay as an image source and an imaging optical arrangement to deliver the image to the eye of a viewer.

The second mode is a Near Projection Display (NPD), which uses a near field 20 projection optical arrangement to provide a projected image on a screen at a near distance of 5 – 25 cm, for example.

The third mode is a Window Mode Display (WMD), where the image appears through a special optical element, which enlarges the exit pupil of the imaging optical arrangement so that the image appearing on the microdisplay is provided as a virtual 25 image to a viewer at a distance.

The fourth mode is Projection Display (PD), whereby the image is projected onto a screen, at a distance of 0.5m - 2.5m from the device, and the real image appears to be up to 1 m in diagonal, for example.

According to the present invention, an optical engine is used to form an image 30 based on the optical arrangements of each mode of operation of the device. The optical engine consists of an image source, such as a microdisplay device, a light source, one or

more lenses for collecting light from the light source for illuminating the image source, other optical elements and one or more lenses which form the imaging optics. A number of different lens arrangements are used to achieve the desired display modes. The internal light source, powered by one or more batteries in the portable device, is used for 5 illumination in the first three modes. For projecting an image at a screen disposed at a distance from the portable device, however, an external light source may be needed. Preferably, the illuminating light from the external light source is brought to the portable device via an optical light guide.

Accordingly, the present invention provides a portable device having a plurality of 10 selectable display modes for providing an image to a viewer, the portable device comprising:

- an image source;
- an illuminating light source for providing illuminating light to the image source for providing output light from the image source;
- 15 a first optical arrangement for forming the image from the output light along an optical path of the first optical arrangement; and
- a second optical arrangement, disposed in the optical path, for modifying the image forming of the first optical arrangement.

According to the present invention, the selectable display modes include:  
20 a first mode for allowing the viewer to perceive the image by placing an eye in the optical path adjacent to the portable device;  
a second mode for allowing the viewer to perceive the image formed on a surface disposed in the optical path adjacent to the portable device;  
a third mode for allowing the viewer to perceive the image by placing the eye in 25 the optical path at a distance from the portable device; and  
a fourth mode for allowing the viewer to perceive the image formed on a surface disposed in the optical path at a distance to the portable device.

The present invention will become apparent upon reading the description taken in conjunction with Figures 1 to 7.

Brief Description of the Drawings

Figure 1 is a block diagram showing some of the basic components in a portable device, according to the present invention.

20 Best Mode for Carrying Out the Present Invention

The portable device 1, according to the present invention, uses an optical engine 16 and different optical arrangements to provide an image to a viewer in different display modes. The portable device 1 can be a mobile phone, a personal digital assistant (PDA), a communicator and other portable electronic devices. Preferably, the portable device 1 25 has a housing 10 to house a communication unit 12 for receiving and transmitting information from and to an external device, a controlling and processing unit 14 for handling the received or transmitted information. More particularly, the controlling and processing unit 14 is operatively connected to the optical engine 16 for providing image data to the microdisplay device 32, 32' or 32" to display an image thereon (see Figures 2a to 2c). In addition, the portable device 1 comprises an internal light source 20 for providing illuminating light to the optical engine 16, if necessary, and an internal power

source 22 for providing power to the internal light source 20. The internal power source 22 may contain one or more batteries. Moreover, when the optical engine 16 is used for projecting a real image at a distance screen, it may be necessary to bring in a light beam from an external light source. Thus, it is preferable to have a connector 24 for connecting 5 one end of a light guide 70 to the portable device 1 (Figures 6 and 7). In order to select the display modes, it is preferable to have a device 18 to select different optical arrangements for different display modes.

The optical engine 16, according to the present invention, may comprise a reflective-type microdisplay 32, a transmissive-type display 32', or an emissive-type 10 display 32" as an image source. As shown in Figure 2a, one or more lenses 30 are used to collect light 100 from the internal light source 20, or the light beam 100' brought in by the light guide 70, and expand the collected light into a broad beam 102 for illuminating the microdisplay 32. One or more lenses 36 are used to collect output light from the microdisplay device 32 for forming an image. As shown in Figure 2a, a beam-splitter 34 15 is used to fold the optical path of the illuminating beam 102. More particularly, the beam splitter 34 is a polarizing beam-splitter (PBS) and the reflected light beam 102 is s-polarized. With such an arrangement, the light beam 104 that provides an image to a viewer is p-polarized.

When a transmissive-type microdisplay device 32' is used as an image source, as 20 shown in Figure 2b, it is possible to dispose the microdisplay device 32' between the illuminating optics 30 and the imaging optics 36 without folding the optical path of the expanded beam 102. Preferably, polarizers 40, 42 of different polarization axes are used to provide light beams with orthogonal polarization.

When an emissive-type microdisplay device 32" is used as an image source, as 25 shown in Figure 2c, no illuminating optics nor light source is needed. With an emissive-type microdisplay device 32", the optical engine 16 may not have sufficient light for projecting a real image at a distance screen.

It is understood that the image-forming beam 104 is propagated along an optical path 130 defined by the imaging optics 36. In order to view the image displayed on the 30 microdisplay device 32, 32', 32", one must place an eye or an object in the optical path 130. The imaging optics 36, in the simplest case, is just a magnifying lens. In more

complex cases, there might be several optical elements. In order that the imaging optics 36 in the optical engine 16 can be rearranged or reconfigured to form an image according to the mode of operation of the device 1, it is preferred that the imaging optics 36 comprise a plurality of lenses and other optical components.

5 The optical engine 16 is designed in such a way that, in the NED configuration, a viewer 150 can directly view the image formed by the imaging optics 36 by placing an eye in the optical path 130 adjacent to the portable device 1, as shown in Figure 3. In this NED mode, the image provided by the optical engine 16 is a virtual image. The size of the perceived image can be slightly or significantly larger than the microdisplay device 32 itself. In the NED mode, the power consumption is low. Thus, it is possible to use the internal light source 20 for illumination. The internal light source 20 may comprise one or more light-emitting diodes powered by one or two batteries in the portable device 1, for example, but it is also possible to use a different type of lighting device.

10 Figure 4 shows an optical arrangement for the near projection display (NPD) mode. When the portable device 1 is used in the NPD mode, the imaging optics 36 are rearranged or reconfigured to form a real image on a surface or screen 60. A reflecting surface 62, such as a first surface mirror, is used to fold the optical path of the image-forming beam 106. Preferably, the projected image is in the order of 10 cm in diagonal and the screen is an integral part of the device. Although the power consumption in the 15 NPD mode is expected to be much higher than that in the NED mode, it is still possible to use the internal light source 20 for illumination. Preferably, the screen 60 has such characteristics that the image can be viewed within a reasonably large viewing angle. The system can be used without a folding mirror or, alternatively, several mirrors can be used to fold the image-forming beam 106 in order to minimize the size of the device. It is 20 possible that additional lenses and other optical components are disposed between the optical engine 16 and the screen 60 to reconfigure the NED optics.

25 In the third display mode (WMD), additional optical components are used to extend the exit pupil of the imaging optics 36 in the optical engine 16 so that the virtual image formed by the imaging optics 36 can be viewed at a greater distance from the device. As shown in Figure 5, outgoing light 120 from an exit pupil extender 54 will 30 form a virtual image at a distance from the device 1. The virtual image, as perceived by a

viewer in this WMD mode, can be larger than the physical size of the extender 54 itself because the image appears at a distance. The power consumption of this mode is slightly higher than that of the NED mode, but lower than that of the NPD mode. It is possible to use the internal light source 20 for illumination.

5 The fourth display mode of the portable device 1, according to the present invention, is illustrated in Figure 6. When the device is used in the fourth display mode, the imaging optics 36 are rearranged or reconfigured to project the real image by an image-forming beam 108 to a larger screen 64 at a larger distance. In this display mode, it is required that an external light source is used to provide an intense light beam to  
10 illuminate the microdisplay 32, 32'. To achieve this display mode, it is preferable to use a light guide 70 to convey an illuminating light beam from an external light source 80 (Figure 7) to the portable device 1 through the connector 24. It is possible to use additional lenses and other optical components disposed between the optical engine 16 and the screen 64 to reconfigure the NED optics.

15 The light source for projection is typically a discharge lamp, such as an Ultra High Pressure (UHP) Mercury lamp. The efficiency of such a lamp is typically only about 10%, and the rest of the power is converted to heat. Quite a significant part of the heat is Infra Red (IR) radiation, which can overheat the microdisplay and cause severe damage to the portable device itself, or even destroy it within a short time. This problem is  
20 compounded by the fact that there would not be sufficient space in the portable device to include an effective cooling system to dissipate the heat associated with the light source. Thus, an external light source 80, such as the one shown in Figure 7, must be used, instead of the internal light source 20.

25 As shown in Figure 7, a lamp 84 with a reflector is used as a light source. The lamp 84 is powered by a power supply 82. The light output from the lamp is filtered by an IR/UV filter 86 and focused into the light guide 70. Preferably, a light sequencer 88 is provided in the light path to turn the light beam to the light guide 70 into sequential colors under the control of the portable device 1. As shown in Figure 7, an electrical cable 72 connecting the portable device 1 to the external light source 80 allows the portable device  
30 1 to send a control signal to the light sequencer 88 according to the selected display mode.

In summary, the portable device, according to the present invention, includes an optical engine, which is adapted to form an image according to one or more display modes. The portable device is designed such that the change between different display modes can be easily carried out.

5 Although the invention has been described with respect to a preferred embodiment thereof, it will be understood by those skilled in the art that the foregoing and various other changes, omissions and deviations in the form and detail thereof may be made without departing from the spirit and scope of this invention.
